Determination of fluoride in tea using a combustion ion chromatography system

Authors

Hua Yang, Daniel Khor, and Jeff Rohrer Thermo Fisher Scientific, Sunnyvale, CA

Keywords

U.S. EPA, Small particle column, Integrion, IonPac AS18-4µm column, China national standard, NY659-2003, NY/T 838-2004

Goal

To develop a simple method to determine fluoride in tea using combustion ion chromatography (CIC), including a Mitsubishi Automatic Combustion Unit Model AQF-2100H system and a Thermo Scientific[™] Dionex[™] Integrion[™] HPIC[™] system.

Introduction

Consumption of excessive amounts of fluoride can lead to dental fluorosis, bone fractures, and skeletal fluorosis. Currently, the U.S. EPA has an enforceable drinking water standard of 4.0 ppm for fluoride with a non-enforceable secondary standard of 2.0 ppm to protect children against tooth discoloration and/or pitting.¹

Tea is an important product for China's economy. However, all tea plants have an affinity for fluoride. Indiscriminate consumption of tea can lead to increased levels of fluoride in the body, especially if the tea is brewed with fluoridated water. China national standard NY659-2003 sets a limit of 200 ppm fluoride for tea.² The current standard method for determining

fluoride in tea is NY/T 838-2004,³ which is an ionselective electrode method. It requires preparations of strong oxidizing perchloric acid solution and total ionic strength adjustment buffer (TISAB) solution before measurement. For each measurement, more than 60 min of lab work is needed: weigh the tea sample, add into 25 mL perchloric acid solution, stir for 30 min, add 25 mL TISAB solution, stir for another 30 min, and then determine the fluoride concentration using a fluorideselective electrode. The electrode also needs to be thoroughly washed and reconditioned before each new measurement. This method is lengthy, unsafe, and tedious.

Ion chromatography (IC) is the most sensitive and versatile method for the determination of halides (including fluoride). However, determining fluoride in brewed tea is problematic because organic acids that elute near fluoride can impact quantification and brewing time and water hardness affect fluoride release from tea.⁴ Combustion IC (CIC) has been demonstrated for many applications, such as the determination of halogens in coal.⁵ Using CIC, samples are oxidized (oxidative pyrolysis) at temperatures of about 1000 °C. The combustion byproduct gases, including HX and SO_2 / SO_3 , are passed through an aqueous absorbing solution, and then directly injected into the IC instrument, thereby eliminating the sample matrix and any associated interferences.

This application note shows development of a simple CIC method to determine fluoride in tea. The CIC system used for this method is comprised of a Mitsubishi[®] Automatic Combustion Unit Model AQF-2100H system and a Dionex Integrion HPIC system equipped with the Thermo Scientific[™] Dionex[™] IonPac[™] AS18-4µm column set.

Experimental

Equipment

Mitsubishi Automatic Combustion Unit Model AQF-2100H system, including:*

- Automatic Boat Controller Model ABC-210
- Liquid Sample Changer Model ASC-250L
- Horizontal Furnace Model HF-210
- Gas Absorption Unit GA-210
- External Solution Selector ES-210

Dionex Integrion HPIC system including:

- Dionex Integrion HPIC system pump
- CD Conductivity Detector
- Detector Compartment Temperature Control
- Column Oven Temperature Control
- Tablet Control
- Consumables Device Tracking Capable
- Eluent Generation

 * Equivalent results can be achieved using an Automatic Boat Controller with solid sample changer.

Table 1 lists the consumable products needed for the Dionex Integrion HPIC system configured for suppressed conductivity detection.

Table 1. Consumables list for the Dionex Integrion HPIC system.

Product Name	Description	Part Number
Thermo Scientific [™] Dionex [™] IC PEEK Viper [™] Fitting Tubing Assembly Kits	Dionex IC Viper fitting assembly kit for the Integrion RFIC system with CD: Includes one each of P/Ns: 088805–088811	088798
	Guard Column Out to Separator Column In: 0.007 in i.d., 4.0 in long (102 mm)	088805
	Injection Valve, Port C (Port 2) to Guard Column In: 0.007 in i.d., 5.5 in long (140 mm)	088806
Dionex IC PEEK Viper Fitting	EGC Eluent Out to CR-TC Eluent In: 0.007 in i.d., 6.5 in long (165 mm)	088807
Tubing Assemblies	Separator column Out to Suppressor Eluent In: 0.007 in i.d., 7.0 in (178 mm)	088808
	Suppressor Eluent Out to CD In: 0.007 in i.d., 9.0 in long (229 mm)	088810
	CR-TC Eluent Out to Degasser Eluent In: 0.007 in i.d., 9.5 in long (241 mm)	088811
Thermo Scientific [™] Dionex [™] EGC 500 KOH Eluent Generator Cartridge	Eluent generator cartridge	075778
Thermo Scientific [™] Dionex [™] CR-ATC 600 Continuously Regenerated Anion Trap Column	Continuously regenerated trap column used with Dionex EGC KOH 500 cartridge	088662
HP EG Degasser Module	Degasser installed after Dionex CR-TC trap column and before the Injection Valve. Used with eluent generation	075522
Thermo Scientific [™] Dionex [™] AERS [™] 500 Carbonate Electrolytically Regenerated Suppressor	Suppressor for 4 mm columns	082540
Thermo Scientific™ Dionex™ IonPac™ AG18-4µm Guard Column	Anion guard column, 4×30 mm	076035
Thermo Scientific [™] Dionex [™] IonPac [™] AS18-4µm Analytical Column	Anion analytical column, 4 × 150 mm	076034
Thermo Scientific™ Nalgene™ Syringe Filter	Syringe filters, 25 mm, PES membrane, 0.2 µm This type is compatible with IC analysis.	Thermo Scientific 7252520*

* Fisher Scientific P/N 09-740-113

Software

- Thermo Scientific[™] Chromeleon[™] Chromatography Data System (CDS) Software, version 7.2 SR4 MUb (8525)
- Mitsubishi NSX-2100 version 2.1.6.0

Reagents and standards

- Deionized (DI) water, 18 M Ω ·cm resistivity or better
- Dionex IC Standard, Fluoride Standard (1000 mg/L), 100 mL, P/N 037158
- Ammonium fluoride, (Sigma-Aldrich[®], ≥99.99%)

It is important to use DI water for CIC, including in the preparation of standards, eluents, absorption solution, wash solution, and the carry solution. This minimizes system contamination and thus improves method sensitivity.

Stock standard solution

To prepare the 2000 ppm fluoride stock standard, 389.9 \pm 0.1 mg of ammonium fluoride was accurately weighed into a 100 mL volumetric flask and ~50 mL of DI water was added. The flask was swirled to dissolve the ammonium fluoride, filled to the mark with DI water, and then mixed thoroughly. The stock standard was stored at 4 °C and was stable for one month. Because ammonium fluoride sublimates when heated, this fluoride stock standard can be used for either IC or CIC.

Working standard solutions

Working standard solutions were prepared for the External Solution Selector ES-210 by diluting the Dionex IC Fluoride Standard (1000 mg/L) or the 2000 ppm ammonium fluoride stock standard with DI water (Table 2).

Working standard solutions were prepared for the Liquid Sample Changer Model ASC-250L by diluting the 2000 ppm ammonium fluoride stock standard with DI water (Table 3). The Dionex IC Fluoride Standard is not recommended here because it is prepared from its sodium form, which causes quartz devitrification at high concentration.

Samples

Three tea samples were obtained from stores in China and were stored at room temperature:

- Tea 1 was in an individually sealed vacuum package, about 7 g/package.
- Tea 2 was in a sealed paper package with a GB/T18650 label.
- Tea 3 was originally in a sealed plastic package but had been previously opened for about a year.

Table 2. Concentration of working standards for the ES-210.

Calibration Level	1	2	3	4	5	6	7	8
Concentration (ppm)	0.002	0.005	0.02	0.05	0.20	0.5	1.00	2.00

Table 3. Concentration of working standards for the ASC-250L.

Calibration Level	1	2	3	4	5	6	7	8
Concentration (ppm)	4.0	10.0	50.0	100	200	500	1000	2000

To prepare tea samples for fluoride determination, at least 25 g of tea for each tea sample was ground using an electric coffee grinder and the tea sample was dried at 100 °C overnight (>14 h) if the package was previously opened.

The following samples were also included in this work for comparison:

- Tea samples directly from the package without grinding.
- Freshly ground tea samples without drying. Tea samples 1 and 2 were ground immediately after the package was opened.
- Ground tea sample 3 dried at 100 °C for 1 h.

To understand the fluoride distribution when brewing tea, the tea was dried overnight, 5 g of the dried tea was soaked in 50 g of boiled DI water (~100 °C) for 5 min, the tea solution was filtered, and the fluoride in the tea solution was measured using CIC. The remaining fluoride in the brewed tea (solid) was measured using CIC after rinsing the tea twice with DI water, drying it at 100 °C overnight, and grinding it. For comparison, 1000-fold diluted filtered tea solution was directly injected into the IC through the External Solution Selector ES-210 (i.e. a non-combusted sample).

To assess recovery, 20 μ L of a 50 mg/L or 100 mg/L ammonium fluoride solution were added into the 20 mg tea sample in the sample boat using a 100 μ L syringe.

Determination of fluoride in tea

Fluoride in tea is determined by CIC using the Constant Volume mode. There are two methods for calibration. Method 1 uses direct injection of liquid standards through the External Solution Selector ES-210. For this method, the weight of each tea sample and dilution factor need to be entered into the data sequence pane of the Chromeleon CDS software console window to calculate the concentration of fluoride in the tea sample. The dilution correction factor is determined following instructions in the Mitsubishi Automatic Combustion Unit Model AQF-2100H manual⁶. The dilution factor is around 10,000 when a 10 mL absorption tube is used. Method 2 uses injection of liquid standards through the Liquid Sample Changer Module ASC-250L. Because both standards and samples are combusted in the same way, the dilution correction factor is not needed. Only the weight of each tea sample needs to be entered into the data sequence pane of the Chromeleon CDS software.

Instrument setup and installation

Follow TN72211 to setup the system for this application.⁷ The Mitsubishi Automatic Combustion Unit Model AQF-2100H system was connected to the Dionex Integrion HPIC system according to Figure 1.

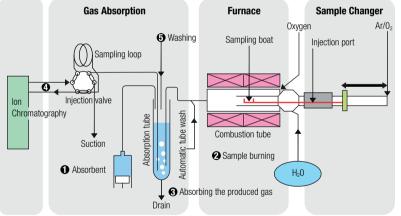

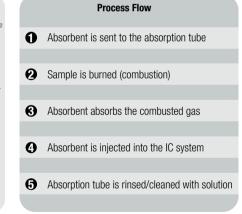

Figure 1. Diagram of a combustion ion chromatography (CIC) setup.

The Dionex Integrion HPIC system is a high-pressurecapable integrated RFIC system designed for high pressure eluent generation under conditions up to 5000 psi. The details on preparing an IC system for the analysis can be found in TN 175.⁸ The key steps include:

- Configuring the modules in the Chromeleon CDS software
- Plumbing the high pressure Dionex Integrion HPIC system
- Conditioning electrolytic devices and columns according to their product manuals
- Starting the Dionex Integrion HPIC system
- Creating an Instrument Method

Results and discussion

Compared to the current standard test method for fluoride in tea (NY/T 838-2004)3, which needs more than one hour with many manual steps for sample preparation, this method is short and simple. As illustrated in Figure 1, after placing the boat containing the weighed tea sample into the sample changer, the sample is sent to the furnace and combusted for about 10 min using the combustion conditions listed in Table 4. The combusted gas is absorbed by DI water and is then analyzed by IC in 10 min (Table 5). This automated method requires about 20 min per sample. By overlapping the functions of the IC and the combustion unit, the time is shortened to about 11 min per sample.

In this application note, calibration method 1 was used to determine fluoride in tea samples. The IC system was calibrated by direct injection of fluoride standards through the External Solution Selector ES-210. To determine the linear calibration ranges, the peak area responses to concentration were determined using a minimum of triplicate injections of calibration standards over the calibration range of 0.002 to 2.00 mg/L. The calibration was linear with $r^2 = 0.9993$. However, a quadratic calibration ($r^2 = 1.0000$) was used here because it was a better fit for the data and should therefore provide a more accurate determination of the fluoride in the tea sample with dilution factor of 10,000. Figure 2 shows the quadratic calibration curve. The method detection limit (MDL) of the IC method was determined following the guidelines outlined in USP General Chapter, Validation of Compendial Methods.⁹ It is calculated by > 7 injections of the lowest calibration standard 0.002 mg/L, and MDL = $3.14 \times \sigma$ (standard deviation) = 0.0002 ppm. Table 6 summarizes the calibration and MDL of the IC method.

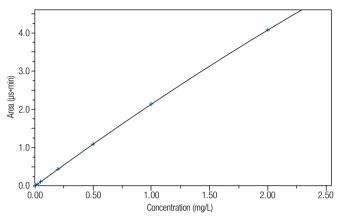

Figure 2. Fluoride calibration curve from 0.002 to 2.00 mg/L.

(MDL) for fluoride

	i nuonue.			
Calib Rang (ppm	е	Calibration Type	Coefficient of Determination (r ²)	MDL (ppm)
0.002-	2.00	Quadratic	1.000	0.0002
0.002-	2.00	Linear	0.9993	0.0002

Table 6. Summary of calibration and the IC method detection limit

Figure 3 shows a comparison of the chromatograms of the brewed tea solution when directly injected to IC and when introduced through CIC by the Liquid Sample Changer Model ASC-250L. The chromatogram of the tea solution without combustion shows several peaks, presumably organic acids, either eluting near or coeluting with fluoride. As a result, the determined amount of fluoride in tea exceeds the actual value. The combustion process converts organic acids to carbon dioxide and water; therefore, fluoride analysis is simplified. As seen in Figure 3, the CIC chromatogram of the same tea solution shows a clean fluoride peak, leading to accurate quantitation.

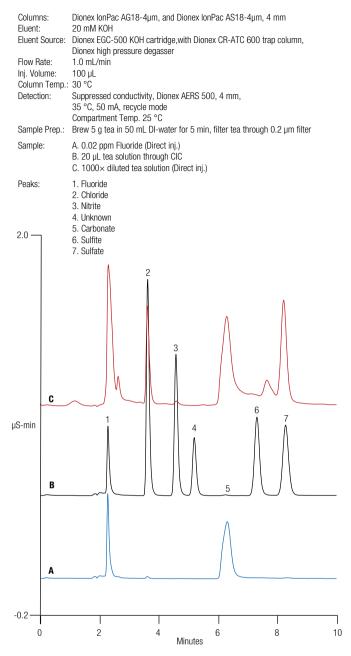

Table 7 shows fluoride distribution when brewing 5 g of dried Tea 3 in 50 g of boiled DI water (~100 °C) for 5 min. A significant portion (41%) of the fluoride remained in the brewed tea leaf. Therefore, the solid tea sample, not the brewed tea solution, should be used to determine the total fluoride content.

Figure 4 shows CIC chromatograms of a 200 ppm fluoride standard and about 20 mg of the three tea samples. The peaks of fluoride, chloride, nitrite, sulfite, and sulfate indicated that F, CI, N, and S are present in all three teas. The fluoride levels vary among samples: 279 ppm in Tea 1, 55 ppm in Tea 2, and 129 ppm in Tea 3.

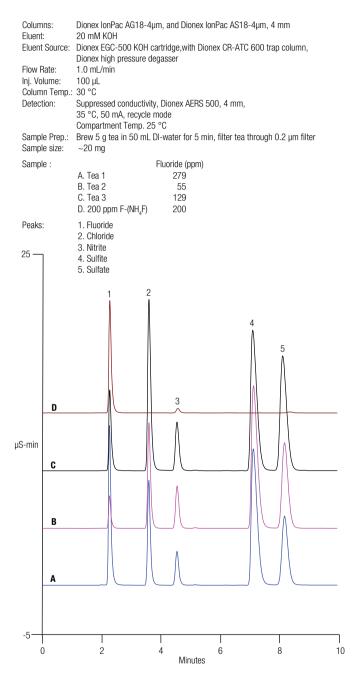

Figure 4. Combustion IC chromatograms of standard and teas.

Table 7. Distribution of fluoride in tea after brewing.

	Fluoride (ppm)	n	% Fluoride
Fluoride in brewed tea	77±4	3	59
Fluoride remaining in the tea after brewing	54±10	3	41

In the development of this CIC method, different sample preparations were explored. Table 8 shows the results of fluoride in Tea 3 with different preparations. The results suggest that not all of the tea within a single package is homogeneous with respect to fluoride. The most consistent results are achieved by grinding the tea. Therefore, grinding is the recommended sample preparation for this analysis. The drying test also indicated that drying overnight at 100 °C is necessary for fluoride recovery. The CIC method performance was measured by recovery of known fluoride standards. The standards from 4 to 2000 ppm were introduced using the Liquid Sample Changer Module ASC-250L and combusted. The fluoride concentration was then measured using calibration method 1. Table 9 summarizes the results. From 10 to 2000 ppm, the method is accurate with $100\pm5\%$ compared to its actual value. The repeated combustion of the 4.0 ppm standard was used to determine the MDL of the combustion CIC method for tea following the same guidelines.⁹ The MDL of the combustion CIC method for tea was determined to be 1 ppm.

Table 8. Fluoride in Tea 3 with different sample preparations.

Tea Sample and Replicate	Fluoride (ppm)	Average
Tea leaf 1 (19.70 mg)	137

2000.0	2055	1	103

The results of the fluoride determinations in Tea 1, Tea 2, and Tea 3 are shown in Table 10. Both Tea 1 and Tea 2 were in sealed packages before grinding. As no difference was observed before and after drying Tea 1 and Tea 2 samples, all data points were used to calculate the average fluoride content in these two teas. The determined fluoride concentrations in teas were as follows: 279±3 ppm in Tea 1, 55±4 ppm in Tea 2, and 129±3 ppm in Tea 3. As sample matrix may impact the precision and accuracy, method performance was also evaluated using spike recovery in tea samples. Table 11 shows the results of the spike recoveries of fluoride in three teas. When spiking either 50 ppm or 100 ppm of fluoride, the calculated recoveries were from 95% to 116% for all samples. The CIC method to determine fluoride in tea exhibits good precision and accuracy.

Table 10. Fluoride in Tea 1, Tea 2, and Tea 3.

Sample	Measurement Time	Fluoride (ppm)	Average	RSD
Tea 1 Freshly ground	Day 1 Day 2	280±3 (n=3) 278±5 (n=3)	279±3 (n=13)	1
without drying	Day 2 Day 3	279±2 (n=3)	279±0 (II=10)	I
Tea 1 Ground and dried at 100 °C overnight	Day 4	278±3 (n=4)	279±3 (n=13	1
Tea 2 Freshly ground without drying	Day 2	55±5 (n=9)	55±5 (n=20)	8
Tea 2 Ground and dried at 100 °C overnight	Day 4 Day 5	57±3 (n=3) 53±4 (n=8)	55±5 (n=20	8
Tea 3 Ground and dried at 100 °C overnight	Day 4	129±3 (n=6)	129±3 (n=6)	2

Table 11. Recovery of fluoride in tea.

Sample	Fluoride (ppm)	Recovery* (%)	Average recovery (%)
	337	116	
Tea 1 (279 ppm F ⁻) 50.0 ppm spiked	330	103	111±7 (n=3)
50.0 ppm spiked	336	114	
	109	107	
Tea 2 (55 ppm F⁻) 50 ppm spiked	108	104	103±6 (n=3)
50 ppm spiked	104	95	
T 0	155	99	
Tea 2 100 ppm spiked	153	97	99±1 (n=3)
Too ppm spiked	155	99	
Tea 3 (129 ppm F [_]) 100 ppm spiked	229	101	

Conclusion

This application note demonstrates a simple CIC method to determine fluoride in tea. Using the CIC system, fluoride in tea is determined in 20 min (11 min if the combustion and chromatography functions are overlapped), a significant time savings over the current Chinese national method. The CIC method is sensitive (MDL=1 ppm), precise, and accurate. The only sample preparation required is to grind and dry the tea.
