

A Fresh Approach to ASTM D5769 Analysis using a Thermo Scientific ISQ 7610 Single Quadrupole GCMS

Amit Gujar, Kenneth Free and James Pachlhofer
Thermo Fisher Scientific, Austin, TX, USA

■ The world leader in serving science

Agenda

- Introduction to ASTM D5769
- Introduction to Thermo Scientific GC, GC-MS systems
- Thermo Scientific XLXR™ detector system
- Instruments and instrument method used in this study
- Analysis requirements of ASTM D5769
- Results and discussions of this study
- Summary and conclusion

What is ASTM D5769

- Method to determine aromatics in gasoline by GC-MS
- Benzene, Toluene and Total Aromatics are reported
- Uses Internal standard calibration (3 IS or 4 IS)

Peculiarities of this method

- % level analysis without dilution
 - High split flows (split ratios between 250:1 to 700:1)
 - Low injection volumes (0.1-0.5 µL)
 - “detune” the MS in order to avoid detector saturation

Designation: D5769 – 20

Standard Test Method for Determination of Benzene, Toluene, and Total Aromatics in Finished Gasolines by Gas Chromatography/Mass Spectrometry¹

This standard is issued under the fixed designation D5769; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope*

1.1 This test method covers the determination of benzene, toluene, other specified individual aromatic compounds, and total aromatics in finished motor gasoline, including gasolines containing oxygenated blending components, by gas chromatography/mass spectrometry (GC/MS).

1.2 This test method has been tested for the following concentration ranges, in liquid volume percent, for the following aromatics: benzene, 0.1 % to 4 %; toluene, 1 % to 13 %; and total (C₆ to C₁₂) aromatics, 10 % to 42 %. The round-robin study did not test the method for *individual* hydrocarbon process streams in a refinery, such as reformates, fluid catalytic cracked naphthas, and so forth, used in the blending of gasolines.

1.3 Results are reported to the nearest 0.01 % for benzene and 0.1 % for the other aromatics by liquid volume.

1.4 This test method includes a relative bias section for EPA spark-ignition engine fuel benzene regulations reporting based on Practice D6708 accuracy assessment between Test Method D5769 and Test Method D3606 as a possible Test Method D5769 alternative to Test Method D3606. The Practice D6708 derived correlation equation is only applicable for blended fuels in the benzene concentration range from 0.0 % to 2.50 % by volume as measured by Test Method D5769. The applicable Test Method D3606 range for benzene is from 0.0 % to 2.47 % by volume as reported by Test Method D3606.

1.5 The values stated in SI units are to be regarded as standard. No other units of measurement are included in this standard.

1.6 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to its use.*

1.7 This international standard was developed in accordance with internationally recognized principles on standardization established in the Decision on Principles for the Development of International Standards, Guides and Recommendations issued by the World Trade Organization Technical Barriers to Trade (TBT) Committee.

3. Terminology

- 3.1 Definitions of Terms Specific to This Standard:
 - 3.1.1 *aromatic, n*—any hydrocarbon compound containing a benzene or naphthalene ring.
 - 3.1.2 *calibrated aromatic component, n*—the individual aromatic components that have a specific calibration.
 - 3.1.3 *cool on-column injector, n*—in gas chromatography, a

Thermo Scientific TRACE 1600 Series GC and ISQ 7610 MS

Efficient use of the resources

Spare backup Thermo Scientific™ iConnect™ modules instead of full GC systems

Interchangeable modules on existing TRACE GC systems (1300 and 1600 series)

Injector and detector modules can be purchased on-line (*SSL, PTV, FID, TCD*)

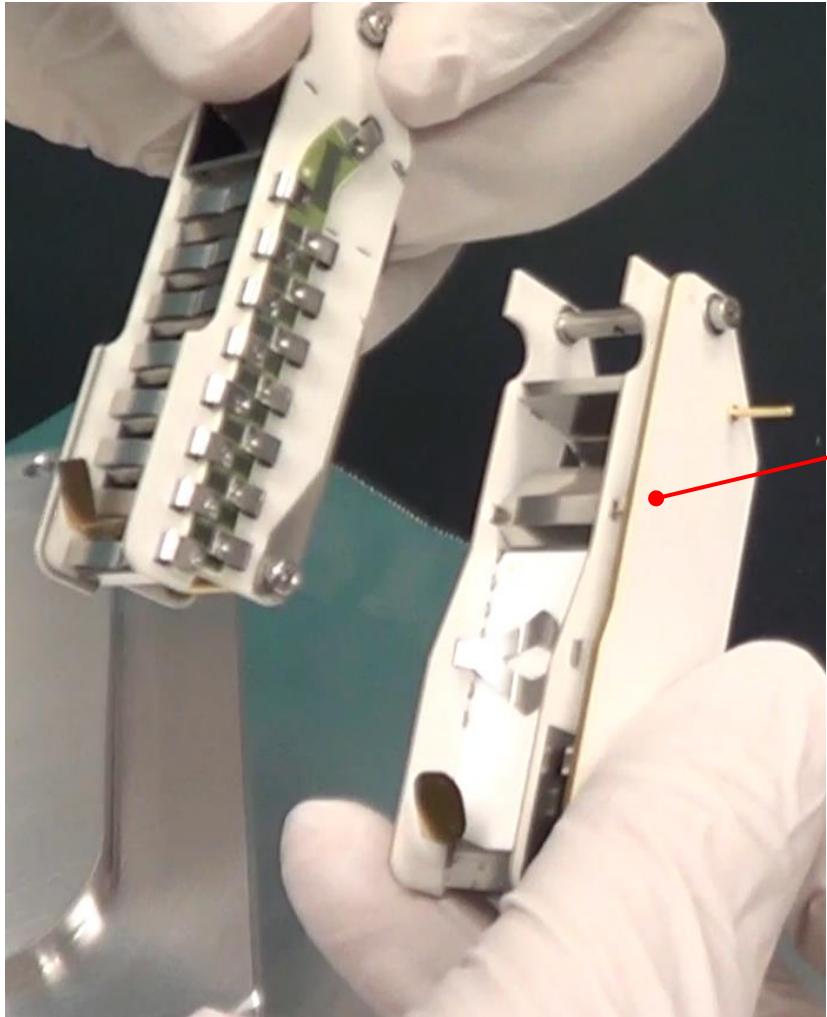

Compact design (44 cm width) for a better use of the bench space

Patented carrier gas saving during operations

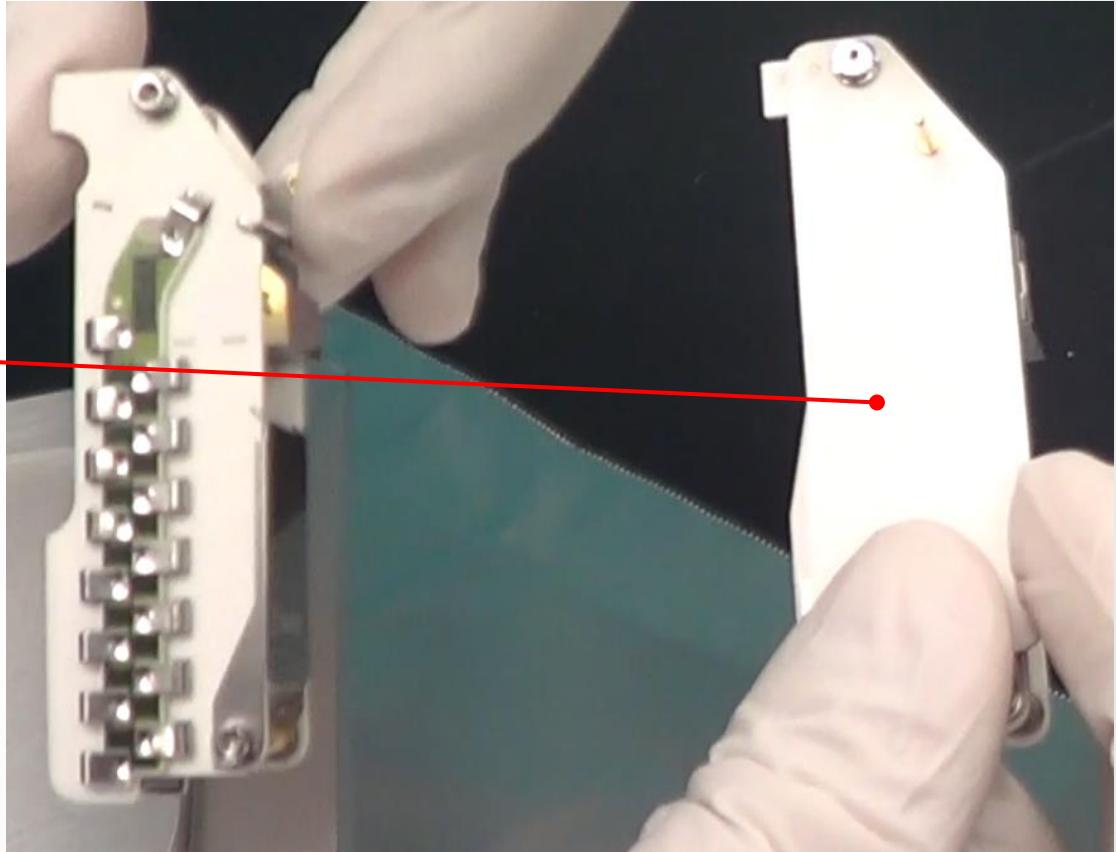

Ability to remove the source and change column without venting the MS

Next Generation Detector (XLXR™ detector system)

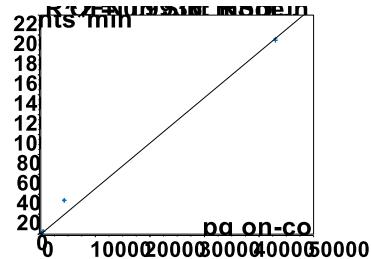

XLXR
detector

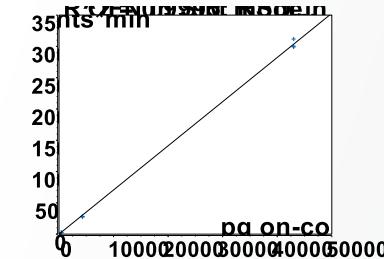

New Detector system includes new EM and change in the electrometer design

Longer lifetime due to new EM and larger dynamic range (2-3 times) because of both EM and electrometer

OFN – 4.3fg to 43ng on-column

Old (EM + electrometer)

New (EM + electrometer)

7 orders of magnitude

Analysis requirements

- Sensitivity test criteria-
 - Solution of 0.01% of 1,4-Diethylbenzene should give signal to noise ratio of at least 5 for m/z 134
- Resolution test criteria-
 - Resolution (R) between 3% of 1,3,5-trimethylbenzene and 1-Methyl-2-ethylbenzene must be equal to or greater than 2.
- Ion check test criteria-
 - Solution of 3% of 1,2,3-Trimethylbenzene will have a fragmentation pattern that meets the below criteria-

Ion, m/z	Relative intensity, %
120	30-60
105	100
91	7-15

- Calibration criteria-
 - r^2 value for the calibration fit should be greater than 0.99
 - A quadratic fit can be used if the deviation of the response factors between the highest standard and the lowest standard is less than 10%
- Quality control reference material check-
 - The values obtained for the quality control standard should be within $\pm 5\%$ of the actual value for all aromatics (except 1,2,4,5-Tetramethylbenzene and naphthalene where it should be within $\pm 10\%$)

24	1,4-Diethylbenzene	23.19	FALSE
25	n-Butylbenzene	23.35	FALSE
26	1,2-Diethylbenzene	23.56	FALSE

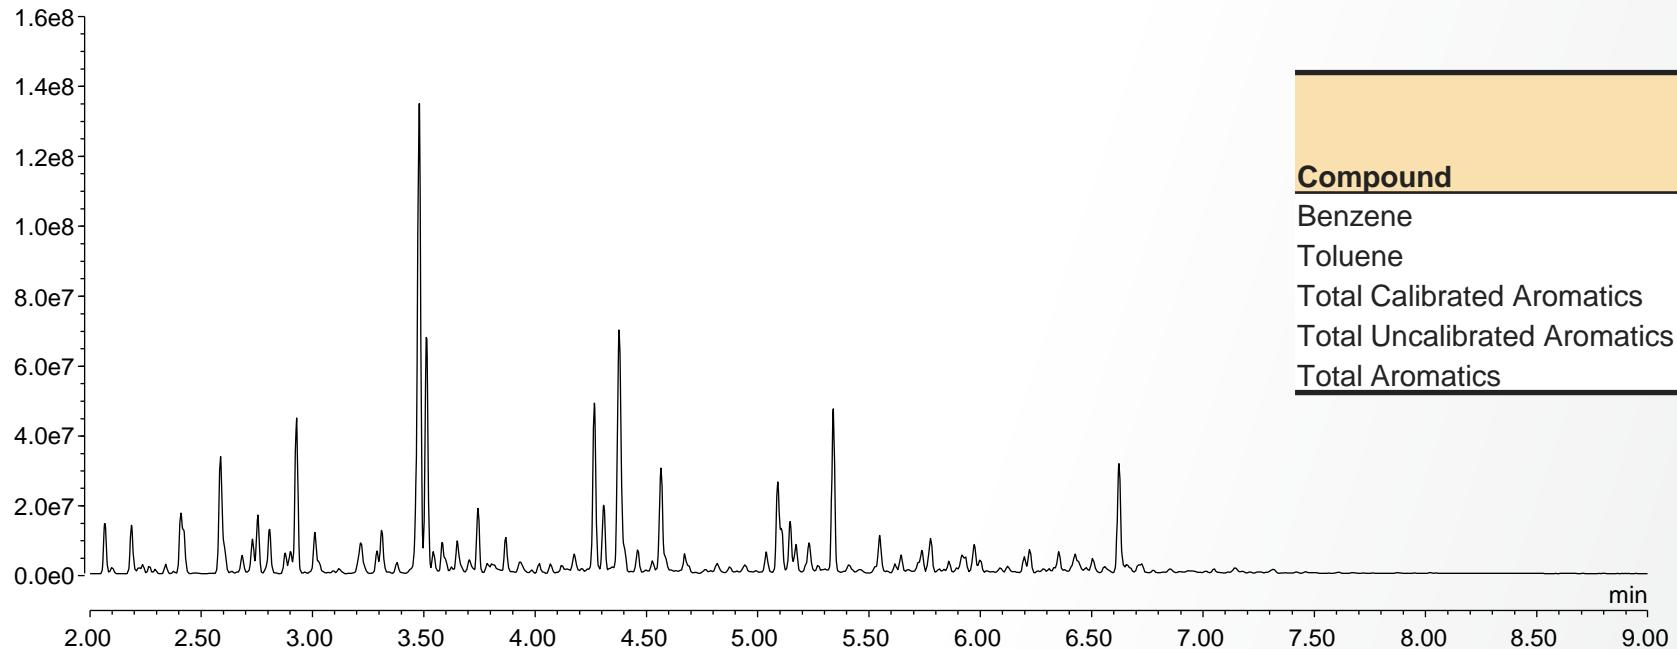

Quality Control Reference material

The values obtained for the quality control standard should be within $\pm 5\%$ of the actual value for all aromatics (except 1,2,4,5-Tetramethylbenzene and naphthalene where it should be within $\pm 10\%$)

Compound	Relative difference (%) between certified and obtained value
1. Benzene	4.70%
2. Toluene	3.50%
3. Ethylbenzene	3.96%
4. m-Xylene	3.46%
5. o-Xylene	4.28%
6. 1,2,4-Trimethylbenzene	1.65%
7. 1,2,4,5-Tetramethylbenzene	0.02%
8. Naphthalene	1.52%

Interlaboratory study (ILS) sample RFG 2101

Compound	Concentration obtained (Vol %)	Z-Score
Benzene	0.48	0.01
Toluene	3.1	0.12
Total Calibrated Aromatics	13.7	n/a
Total Uncalibrated Aromatics	2.6	n/a
Total Aromatics	16.3	0.91

Obtained value is within 1 standard deviation of the mean value

Summary and Conclusion

- Separation of targeted aromatics achieved in under 8 minutes while meeting resolution (Rs) requirements between 1,3,5-trimethylbenzene and 2-ethyltoluene (Rs > 2).
- Linear response observed at %vol concentrations without of detector saturation due to the new XLXR™ detector system.
- Sensitivity obtained by the ISQ 7610 GC-MS system was a factor of 9 times greater than criteria outlined by ASTM Method D5769.
- Ion ratios for 1,2,3-trimethylbenzene passed the method criteria ranges for relative intensity.
- Accurate quantitation was achieved with both a quality control reference standard and interlaboratory gasoline sample, with deviation from reference values well within accepted criteria.

GC-MS, full scan

Goal

The goal of this application note is to demonstrate the capability of the Thermo Scientific™ ISQ™ 7610 single quadrupole GC-MS to deliver accurate quantitation of aromatics in gasoline in accordance with ASTM Method D5769.

Introduction

Monocyclic aromatics, unsaturated hydrocarbons containing a benzene ring, are inherent components of gasoline refined from crude oil. Refineries manipulate the content of aromatics in gasoline to increase the octane rating and overall performance. However, there is considerable concern over the current allowable content of aromatics in gasoline, with growing evidence of their detrimental effects on human and environmental health. The content of benzene, a known carcinogen, in gasoline is restricted to 1.0%¹ with total content of aromatics not to exceed 42%. Thus, gasoline producers must be able to accurately assess fuel purity to ensure compliance with regulatory standards.

The ASTM Method D5769 is a standardized method for the determination of aromatics in gasoline by gas chromatography-mass spectrometry (GC-MS).² A major challenge of performing this analysis is the high content (%vol) of individual aromatics present, which can cause instrument detector saturation. This can result in a non-linear response in the concentration range of gasoline samples, yielding inaccurate quantitation.

Detector linear dynamic range,
spectral fidelity, method consolidation

Introduction

Analytical laboratories that are analyzing food, environmental, pharma, petrochemical, or clinical samples utilize GC-MS or GC-MS/MS for both targeted and known unknowns analysis and employ commercially available libraries such as NIST or Wiley. These laboratories often face challenges when analyzing compounds at both high and low concentrations in a single run. When analytes of interest are present in widely varying concentrations, it can be difficult to accurately quantify the compounds due to the limits of the dynamic range of the mass spectrometer detector system. This leads to the analysis being split into class- or compound-specific methods, which impedes the sample throughput in a laboratory. Even single methods are subject to issues when a very high concentration sample is analyzed on the system, as it cannot be quantified accurately and a repeat analysis must be performed with a diluted sample to bring the concentration of the analyte within the calibration range. This adds further time to the sample analysis and can delay important results getting to clients.

The issues with limited detector dynamic range are not isolated to quantification. When performing sample screening, for example in drugs of abuse analysis, if a compound saturates the detection system due to high concentration, the mass spectral fidelity is affected. This poor spectral quality can lead to poor library matches and potential misidentification of the compound of interest or even a false negative. If the saturation of the detector is identified, the samples can be diluted and re-run; however, this adds to sample processing time and can potentially cause low-level contaminants to be diluted below detection limits and not reported.
